

Visible camera as a solution to information asymmetry / peek problem in Third-person games.

Problem to solve:

In previous games, camera of one players (Player-A) are invisible to another players (Player-B), this makes Player-A able to see player-B without himself or player-B seeing Player-A around certain corner/covers. Thus, creating information asymmetry and gives Player-A unfair advantage.

What Player-B will see in current third person games

Player-A is behind a wall, thus invisible to player-B.

Player-A's camera is out of the wall, can see player-B. Player-B can not see the camera.

A top view of situation

The player-A's camera (invisible to player-B) is already out of the corner, but can provide vision of player-B to player-A without player-B be aware of anything about player-A.

Solution:

To make the information which Player-B can access even. We make the usually invisible camera of Player-A visible to Player-B and any other players, so player-B can use the now visible camera of player-A to determine whether player-A can see him and where roughly player-A is.

What player-B will see

Player-A is behind a wall, thus invisible to player-B.

Player-A's camera is out of the wall, can see player-B. Player-B can now see the camera.

A top view of situation

By making the camera of player-A visible to all players, player-B can see the camera of player-A. Thus, player-B will know he is seen by another player around the corner and is in potential danger. This will greatly reduce information asymmetry and improve fairness in third person games.

Some variants of this idea to further reduce information asymmetry.

An all-player-visible objects like a wire, representation of radio wave communications, single directional arrow head could be used to further indicate precise position of player-A. So player-B as well as any other players can know the position of player-A, if player-A's camera is visible to them.

Variant-1: A bi-directional radio wave icon to show the rough position of player-A to other players.

Variant-2: A bi-directional wire representing the link between player-A and camera to show the rough position of player-A to other players.

Variant-3: A single-directional arrow head to show the rough position of player-A to other players.

Variant-4: A single-directional arrow head to show the rough position of player-A to other players.
